

What did real waiver bids tell us?

A replay of production strategies plus analysis-only Middle VORP and corrected PR #13 curves against 355 anonymized bids from SeaMex 2026. Useful signal, but not enough stable evidence to crown a default.

Evidence window

Reconstructed decision weeks W2 and W3 and W4

Data through

2026-09-30T07:50:30.120Z

Scope

One 32-team league · \$500 FAAB

Five-bullet answer

- Scope: W2, W3 and W4 have same-week reconstructed snapshots. The top three are unique canonical winners after owner-directed-outlier-01 (private GET-only catalog match plus exact position/total fingerprints in both reconstructed snapshots map uniquely to one canonical completed W3 win at \$234; proof matches=1).
- Top-three winning-price arithmetic multipliers (observed/intrinsic): W2: Max VORP 3.34× (3/3); Current-team VoRP 3.38× (3/3); Corrected Safe 2.30× (3/3); Corrected Weeks as Starter 2.84× (3/3); W3: Max VORP 2.35× (3/3); Current-team VoRP 3.00× (3/3); Corrected Safe 1.94× (3/3); Corrected Weeks as Starter 1.94× (3/3); W4: Max VORP 2.74× (3/3); Current-team VoRP 3.02× (3/3); Corrected Safe 2.07× (3/3); Corrected Weeks as Starter 2.21× (3/3).
- Top-three serious-market-median arithmetic multipliers: W2: Max VORP 1.40× (3/3); Current-team VoRP 1.42× (3/3); Corrected Safe 0.92× (3/3); Corrected Weeks as Starter 1.14× (3/3); W3: Max VORP 0.78× (3/3); Current-team VoRP 1.00× (3/3); Corrected Safe 0.65× (3/3); Corrected Weeks as Starter 0.65× (3/3); W4: Max VORP 1.45× (3/3); Current-team VoRP 1.61× (3/3); Corrected Safe 1.11× (3/3); Corrected Weeks as Starter 1.18× (3/3).
- Closest serious-market strategy by eligible weekly cluster: W2 Max VORP; W3 Current-team VoRP; W4 Corrected Weeks as Starter.
- Across all eligible weeks, the closest overall serious-median strategy is Current-team VoRP; raw evidence is retained in the labeled with-target sensitivity view, and weekly scale remains distinct from strategy shape.

Scope guardrail

W2, W3, W4 have like-for-like same-week reconstructed snapshots; earlier-week fallbacks are never backfilled. Aggressive is omitted here because it is derived from Safe.

CLOSEST MEDIAN MARKET

Current-team VoRP

Lowest MAE across owner-directed player/week clusters; competing claims stay within the canonical winner's processing batch.

STRATEGY × SCALE

Separate them

Intrinsic formulas describe target shape; observed/intrinsic multipliers estimate weekly market scale.

PRODUCT DECISION

Hold

3 reconstructed weeks do not support manager-style claims or a production default change.

Middle VORP stays analysis-only.

One shared horizon: $\text{targetTeams} = \max(4, \text{ceil}(\text{teamsRemaining} / 2))$. At the latest reproducible W4 state, 26 teams map to 13. It never maximizes a different stage per player.

Recommendation: retain analysis-only

- Conceptually cleaner than per-player Max VORP stage selection.
- Only W2, W3, W4 are evaluable and all 3 projection snapshots are reconstructed.
- W5+ exact pre-waiver captures must confirm held-out error, bias, rank quality, and 33%/50%/67% stability before any default review.

Privacy-safe current input

W4, 1151 stored rows / 452 supported QB/RB/WR/TE players, hash 9463b40e63b71c00...; aliases only, no league/manager identity or raw payload.

Current-state dollar distributions Full supported QB/RB/WR/TE projection population; positive counts make each method's support explicit.

Rank correlations	Common-horizon sensitivity			
PAIR	Floor/ceiling sensitivity stays explicit; unit tests cover the odd 27→14 versus 13 boundary.			
Middle vs Max VORP	HORIZON	TEAMS	POSITIVE	MEAN
Middle vs Current-team VoRP	67%	18	121	\$8.9
Middle vs Corrected Safe	50% ceiling	13	86	\$7.3
Middle vs Corrected Weeks as Starter	50% floor	13	86	\$7.3
Middle vs 67% horizon	33%	9	59	\$5.5
Middle vs 33% horizon				

Historical common-horizon sensitivity				
Canonical winning bids, owner-directed exclusion applied; odd-team observations keep floor versus ceiling differences visible.				
HORIZON	N	MAE	BIAS	P
67%	20	74.2	-72.3	0.823
50% ceiling	14	100.4	-99.9	0.802
50% floor	14	100.4	-99.9	0.802
33%	12	113.8	-113.8	0.779

Shape is not scale.

Top-three canonical winners and serious market medians use observed bid ÷ intrinsic same-week suggestion. Arithmetic mean is primary; geometric mean, median, and coverage expose ratio skew and zero denominators.

Important metric label

Every value labeled **raw prediction R²*** keeps strategy dollar predictions fixed on the identity line. It is not the goodness-of-fit R² from a regression trained on these bids. Negative values are valid and mean the fixed predictions lose to the observed-mean baseline—not that correlation is negative.

Exact weekly top-three multipliers

Observed/intrinsic; arithmetic mean is primary, with geometric mean, median, and zero-denominator coverage.

Compact with-vs-without sensitivity

private GET-only catalog match plus exact position/total fingerprints in both reconstructed snapshots map uniquely to one canonical completed W3 win at \$234; marker only, with no private identity stored.

VIEW	CLUSTERS	CLOSEST	MAX VORP MAE	CURRENT-TEAM VORP MAE	CORRECTED SAFE MAE	CORRECTED WEEKS AS STARTER MAE
Owner-directed exclusion	41	Current-team VoRP	\$14.0	\$13.8	\$22.9	\$17.3
Raw evidence retained	42	Current-team VoRP	\$14.0	\$13.7	\$22.2	\$17.4

Interpretation boundary

The owner-directed marker is excluded only from this labeled analysis; raw canonical evidence remains in the sensitivity row. Serious means bid > \$5, failed claims must be legitimate same-target competitors, and FAAB-limited observations are marked censored. This supports a strategy-shape × market-scale hypothesis, not individual manager-style conclusions from 3 reconstructed weeks.

Behavioral-question audit appendix

Privacy-safe exact manual app-Week-5 aggregates are supplemented only where explicitly labeled by the W2–W4 reconstructed replay. These provenance classes are not interchangeable.

QUESTION	AVAILABLE EVIDENCE / N	CURRENT ANSWER
Price bands: median / upper quartile / top credible / top all	Exact manual W5 audit: 11 target rows. Top-credible MAE \$36.36, median AE \$25, signed bias +\$16.91, Spearman 0.712; top-all MAE \$47.27, median AE \$48, signed bias +\$40.91, Spearman 0.796.	The ordering signal was useful, but levels were too high overall and errors differed materially by target tier. Privacy-safe median and upper-quartile prediction bands were not retained as a separate deterministic slice, so premium-versus-mid/lower band calibration remains prospective rather than inferred from 11 auctions.
Likely / Possible / Unlikely as claim probabilities and threshold outcomes	Full exact W5 incidence audit: Likely 31/65 (47.7%), Possible 34/108 (31.5%), Unlikely 15/69 (21.7%). Restricted cross-check: 50 manager predictions, 5 canonical claims, 4 observed players, 11 teams.	The labels were directionally ordered for any canonical claim, but separation was weak and the restricted cross-check is tiny. Positive-claim, ≥Max VORP, ≥Safe, ≥serious-median, and ≥observed-minimum bands are not credibly estimable from this one auction; those outcomes remain preregistered prospective tests.
Prior wins, same-position wins, remaining FAAB, and prior-week top bidders	Longitudinal reconstructed replay contains 240 serious bids and 72 winners, but the exact W5 behavioral slice does not contain a clean prior-only panel for these covariates.	No causal or manager-style claim is supported. Effects for prior wins ≥10%/≥20% starting FAAB, prior same-position wins, budget level, and prior-week top-bidder participation/heavy spend remain prospective; budget capacity must be separated from willingness.
Aggressive versus wins and observed minimum proxies	Exact W5, n=11: Aggressive MAE \$26.27 versus winners (bias –\$12.27; 5/11 at or above the winner) and MAE \$18.09 versus observed minimum proxies (bias +\$10.27; 10/11 at or above the proxy).	Aggressive behaved more like a rough threshold than a winning-price forecast, but it was not a reliable minimum: it still missed one observed proxy and commonly exceeded the proxy. Keep it out of the four-method owner multiplier tables because it is derived from Safe.
Aggressive versus 1.5× Max VORP and a cautious tier-aware candidate	Exact W5, n=11: simple 1.5× Max VORP had winner MAE \$36.45 and minimum-proxy MAE \$27.18, worse than Aggressive at \$26.27 / \$18.09. Longitudinal winner replay favors Aggressive in-sample, but no prior-only held-out comparison validates a replacement curve.	The manual audit rejects simple 1.5× Max VORP as an improvement. A cautious tier-aware candidate is only a hypothesis until preregistered exact pre-waiver and held-out evidence exists; no production formula change is warranted.
Prediction distribution and right-tail shape	Only 11 exact W5 target rows; top-all estimates were more upward biased than top-credible estimates.	The sample is compatible with a heavy right tail, but is far too small to identify an exponential or other parametric distribution. Report empirical quantiles only when a larger exact sample exists.
Weekly free-agent rank 1/2/3/later prices	The committed privacy-safe fixture does not retain an exact auction-time free-agent rank with quality, position, injury, active-team, and liquidity controls.	Starting-FAAB shares and Max-VORP/Aggressive multiples by free-agent rank are not credibly estimable here. Preserve this as a descriptive prospective analysis with the named controls.
Claims per manager/auction, alternatives, duplicates, and spend	Exact W5: 107 raw claims, 84 unique manager/player pairs, and 23 additional same-manager alternatives. The owner-team slice had 8 raw and 7 canonical claims.	One auction cannot establish a manager’s “usual claims per auction,” clean claim-count quantiles, or a stable relation to wins/spend. Alternatives and contingency paths must stay separate from canonical claims.
Projected positional need	No privacy-safe, time-aligned roster-need feature with adequate controls is present in the exact behavioral slice or reconstructed replay.	Need-as-predictor is unsupported. Future work must distinguish modeled roster need from observed intent and control for player quality, position, injury, active teams, liquidity, and remaining FAAB.
Do prior-week top bidders bid less next week?	The available exact manual audit is one auction; the reconstructed replay is not a clean prior-only manager panel for this question.	Not estimable. Test raw dollars and starting-/remaining-FAAB-normalized bids prospectively across additional exact auctions.

Owner-team appendix (privacy-safe)

- **Scope:** Exact W5 owner-team slice: 8 raw claims, 7 canonical claims; behavioral cross-check includes 5 canonical claims across 4 observed players.
- **Acquisition / spend / remaining:** One acquisition for \$187 from \$499 pre-waiver FAAB, leaving \$312. Its observed minimum proxy was \$159 and top-credible prediction was \$244, so the clearing price landed inside that wide audit band.
- **Failed contingencies and process quality:** Tiered coverage produced one intended premium acquisition and preserved substantial FAAB, but three later claims were explicitly rejected as roster-full. Contingency/roster-capacity sequencing was therefore imperfect; hidden drop paths are not inferred and failed claims are not treated as clearing competition. This is a process-quality observation, not evidence that the acquisition will produce a good future outcome.
- **Lineup / risk:** Strength: one premium skill-position addition without exhausting budget. Optimized lineup, injury risk, and remaining positional holes are not supported by the privacy-safe post-waiver evidence and are intentionally not fabricated.

Limitation. Three reconstructed auctions plus one exact manual audit do not support stable manager-style, positional-need, longitudinal behavioral, or parametric right-tail claims. Unsupported questions remain prospective hypotheses.

Price fit depends on the question.

Winning-bid error asks who best estimates the clearing price. All-bid error also includes failed claims and token bids. Lower MAE is better; bias shows direction.

Winning-bid scorecard

Sensitivity stays explicit across filters.

These filters were declared before inspecting winners and applied independently. They are sensitivity checks, not permission to delete inconvenient evidence.

Token threshold

Low intent means bid $\leq \max(\$1, 1\% \text{ of original FAAB}) = \5 . Tokens remain in the all-bid view and are separated here.

Three outlier lenses

Ratio-gap flagged 1 isolated top; MAD flagged 3; IQR flagged 4. Independent robust rules test whether one extreme drives the conclusion.

Honest conclusion

Legacy Aggressive is the sample winner. Legacy Aggressive also leads all three predeclared robust filters. Treat this as descriptive evidence, not a default-setting result.

Identity lines expose the misses.

Each dot is an anonymized winning target. A perfect forecast lies on the dashed diagonal; below it underpredicts. Extreme observed bids stretch beyond every intrinsic strategy; Aggressive reaches higher than the others, but still underpredicts the largest win.

EVIDENCE VIEW

Actual vs. predicted: where errors happen

n=72 winning bids per strategy • reconstructed W2-W3-W4 • anonymized targets

* Prediction R^2 is scored against the identity line with no regression refit. It is not fitted-regression R^2 and may be negative.

Manager-adjusted walk-forward forecasts

Measures, assumptions, and guardrails.

All formulas are evaluated on dollars unless marked normalized. Predictions are intrinsic strategy values; manager forecasts are capped at reconstructed pre-bid FAAB.

MAE MAE = (1/n) Σ predicted - actual Average dollar miss. Easy to interpret; extreme bids still matter.	Median absolute error Median AE = median(predicted - actual) The typical dollar miss; less sensitive to a small number of extremes.	Signed bias Bias = (1/n) Σ (predicted - actual) Negative means systematic underprediction; positive means overprediction.
Spearman rank correlation ρ = Pearson correlation(rank(actual), rank(predicted)) Tests whether expensive targets rank above cheap ones. Ties receive average ranks.	Prediction R² (unfitted) R² = 1 - SSE / SST This is the standard predictive score against the observed-mean baseline, but not fitted-regression R². Strategy dollars remain fixed on the identity line. A negative value means they are worse than predicting the observed mean; it does not mean negative correlation.	Normalized FAAB error mean(predicted/FAAB - actual/FAAB) Reported against original \$500 and reconstructed pre-bid manager FAAB. It compares budget share, not willingness.
Cluster-bootstrap interval 2,000 resamples of player × processing-batch clusters Fixed seed 20260927; percentile 2.5%-97.5%. Keeps correlated win/loss claims together. It does not repair snapshot-history error.	Coverage predicted ∈ [lowest serious loss, winning bid] Computed on 26 competitive player/batch clusters. It asks whether a strategy falls inside observed serious bidding range.	Outlier rules ratio ≥ 2× + \$50 gap; MAD > median + 3×1.4826×MAD; IQR > Q3 + 1.5×IQR MAD/IQR also require a \$25 gap; minimum cluster sizes are 3 and 4. Flags are independent and never silently deleted.
Within tolerance predicted - actual ≤ max(\$5, 20% of actual) A practical accuracy band shown alongside continuous error measures.		

Provenance boundary

All 355 formula-usable events use same-week reconstructed W2/W3/W4 projection snapshots and transaction-ledger FAAB reconstruction. Reconstructed means captured after the canonical cutoff; it is not proof of what managers saw. Earlier-week fallbacks are excluded rather than substituted. No identities, league identifier, player names/IDs, manager names/IDs, raw payload, or credentials appear in this artifact. Regenerate deterministically with `npm run analyze:bidding:presentation`.
